Acknowledgements

Preparation of a specification of this kind requires the concerted time and effort of many individuals. The Chair wishes to highlight the efforts of the following contributors to this specification:

Milt Hall
Ron Roman
King Won
Hans Sjöstrand
Andrew Reid
Marc Schwager
Debika Bhattacharya

The Chair especially wishes to thank the editors Kathleen Jarosinski and Rick Raskin for their diligent and timely work.

Gregan Crawford (Test Working Group Chair)

1. Introduction

This specification describes the ATM Test Access Function (ATAF). The purpose of ATAF is to identify methods of access to an ATM cell stream. Three methods of ATAF are specified, Physical Port Mirroring, Virtual Connection Access and Signaling Data Capture. Each method provides a distinct way of monitoring a cell stream. For the purpose of this specification, the word monitoring means observing.

Physical Port Mirroring provides test access to a complete unprocessed cell stream through a physical connection(s) at the switch. Virtual Connection Access provides the capability to access one or more connections (VPC or VCC) via a remotely accessible test access port(s). Signaling Data Capture allows the operator to view data captured from a selected cell stream through a network management system.

2. ATM Test Access Function NE Requirements

The following figure is used as a reference figure to describe the ATM Test Access Function (ATAF) NE requirements.

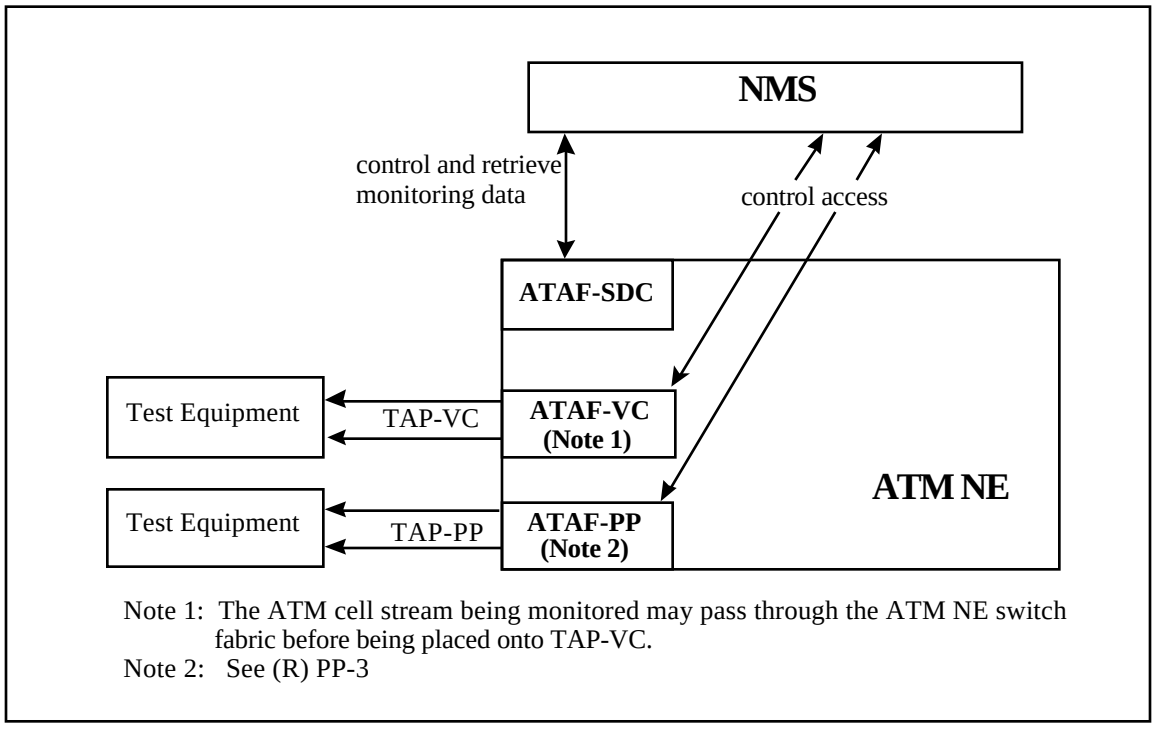

Figure 2-1. ATAF Reference Figure

An ATM NE may choose to support any one, two, or all three categories of ATAF functions:

- ATAF-PP: ATAF Physical Port Mirroring
- ATAF-VC: ATAF Virtual Connection Access
- ATAF-SDC: ATAF Signaling Data Capture.

The remainder of Section 2 provides requirements for:

- ATAF-PP, including its associated Test Access Path (TAP-PP) interface to test equipment, and its optional control link interface to an NMS
- ATAF-VC, including its associated TAP-VC interface to test equipment, and its required control link interface to an NMS
- ATAF-SDC, including its control and data retrieval interface to an NMS.

2.1 ATAF-PP Requirements

2.1.1 ATAF-PP Functional Requirements

ATAF-PP is a monitoring/mirroring function which maps (mirrors) the whole bit stream on a port to a designated monitor port (TAP-PP). No VP/VC selection is involved.

(R) PP-1 ATAF-PP shall provide a method for non-intrusive monitoring of the complete data stream.

There may be many ports within the NE. Selecting a port for monitoring must not affect the traffic on any of the ports.

(R) PP-2 ATAF-PP shall provide access for any ports on the NE.

(R) PP-3 The data stream shall be monitored before the ATM switch performs any cell processing.

This requirement allows the network provider to see exactly what the customer or network provider is sending in the data stream. As an example this would be helpful in analyzing signaling messages with all of their information elements.

2.1.2 TAP-PP Interface Requirements

A TAP-PP is a physical layer connection that carries an ATM cell stream under test from the ATM NE (ATAF-PP function) to the ATM Test Equipment.

(R) PP-4 In order to monitor a single bi-directional ATM connection, two TAP-PP interfaces must be used (one for each direction of traffic being monitored).

(R) PP-5 The TAP shall not degrade the ATM cell stream(s) under test.

(R) PP-6 All traffic on the port being monitored must be mirrored, including signaling, OAM, ILMI, idle cells, etc.

(R) PP-7 The full duplex mirrored traffic streams transmitted by the monitor port(s) to the test equipment must duplicate the original traffic stream(s) in timing, speed, and quality of service parameters.

(R) PP-8 NEs that support ATAF-PP shall provide physical layer connections for the purpose of observing the mirrored cell stream(s).

(R) PP-9 NEs that support ATAF-PP shall provide a method for selecting the port to be mirrored.

(R) PP-10 The physical layer interfaces for TAPs shall be dedicated to ATM test access traffic only; other traffic types (including control link messages) shall not be multiplexed onto these interfaces.

2.1.3 ATAF-PP Control Link Interface Requirements

(O) PP-11 Port selection may be done by means of console commands or a NMS.

(O) PP-12 The ATAF-PP control link interface is an optional feature of ATAF-PP. If provided, it will allow an NMS to control the ATAF physical port mirroring function in the ATM NE. If provided, the NMS shall be able to perform all of the following functions:

- selection of port to be mirrored
- selection of TAP-PP to be used to carry mirrored traffic to test equipment
- activation/deactivation of mirroring function.

2.2 ATAF-VC Requirements

Virtual Connection Access provides the capability to access one or more connections (VPC or VCC) via a remotely accessible test access port.

2.2.1 ATAF-VC Functional Requirements

(R) VC-1 Except for the full splitting test access case which is optional, ATAF-VC shall provide a method for non-intrusive monitoring of the selected logical connection.

There may be many virtual connections within particular data streams. Selecting a virtual connection for monitoring must not affect the other virtual connections.

(R) VC-2 The data stream(s) shall be monitored after the ATM switch performs its cell processing functions.

(R) VC-3 ATAF-VC shall provide test access to any VC including the signaling channels by a remote test system.

(R) VC-4 ATAF-VC shall provide test access to any non-terminated VP by a remote test system.

(R) VC-5 The cell stream(s) available to the remote test system shall contain all valid (except unassigned) cells present at the monitoring point of the monitored connection.

2.2.2 TAP-VC Interface Requirements

TAP-VC is an ATM layer connection that carries an ATM layer cell stream under test from the ATM NE (ATAF-VC function) to the ATM Test Equipment.

(R) VC-6 In order to monitor a single bi-directional connection, two TAP-VC interfaces must be used (one for each direction of the traffic being monitored).

(R) VC-7 The TAP-VC interface shall be provided in accordance with ATM Forum ATM Layer specifications.

2.2.3 ATAF-VC Control Link Interface Requirements

The purpose of the control link is to provide a standard interface for controlling the NE's test access functions from a remote site (e.g., from a centralized network management system).

(R) VC-8 In support of ATAF-VC, the M4 Interface shall provide the management system the ability to connect one direction of a bi-directional ATM cell stream (VCL or VPL) to a TAP-VC, and connect the other direction of the bi-directional ATM cell stream to a second TAP-VC.

(R) VC-9 The M4 Interface shall provide the management system the ability to disconnect an ATM cell stream from a TAP-VC.

(R) VC-10 The ATAF-VC shall allow selection of the ATM cell stream under test as follows:

- VC - Selectable by interface identification and VPI/VCI
- VP - Selectable by interface identification and VPI

(O) VC-11 The M4 Interface shall support management system requests to change the test access mode of an accessed ATM cell stream among the following test access modes: monitor traffic leaving NE (see Figure 2-2), monitor traffic entering NE (see Figure 2-2), split away from NE (see Figure 2-3), split towards NE (see Figure 2-4).

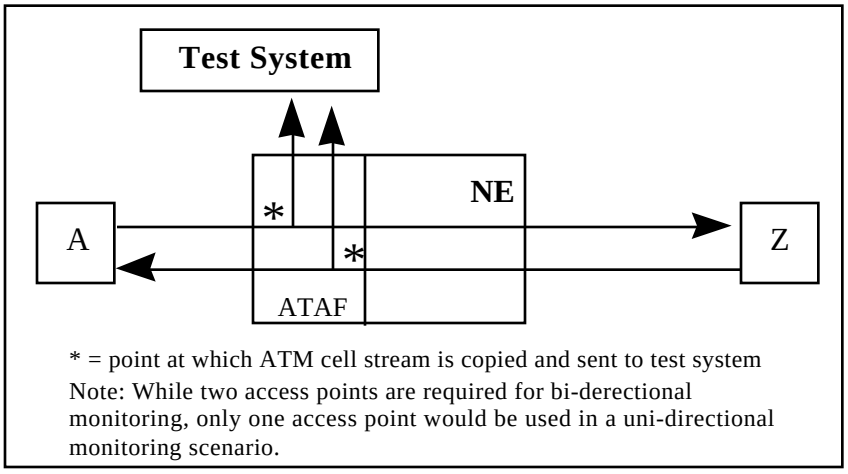

Figure 2-2. "Monitoring" Test Access

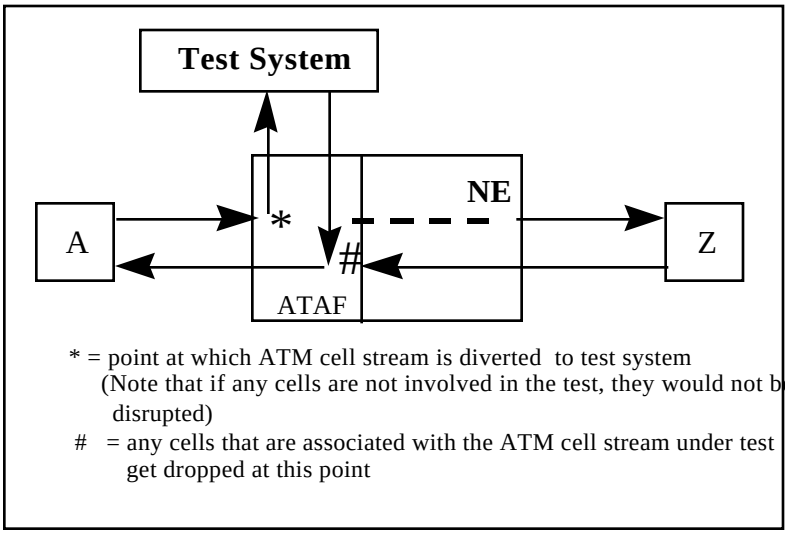

Figure 2-3. "Full-Splitting" Test Access
(Split Direction is Away from NE (Optional))

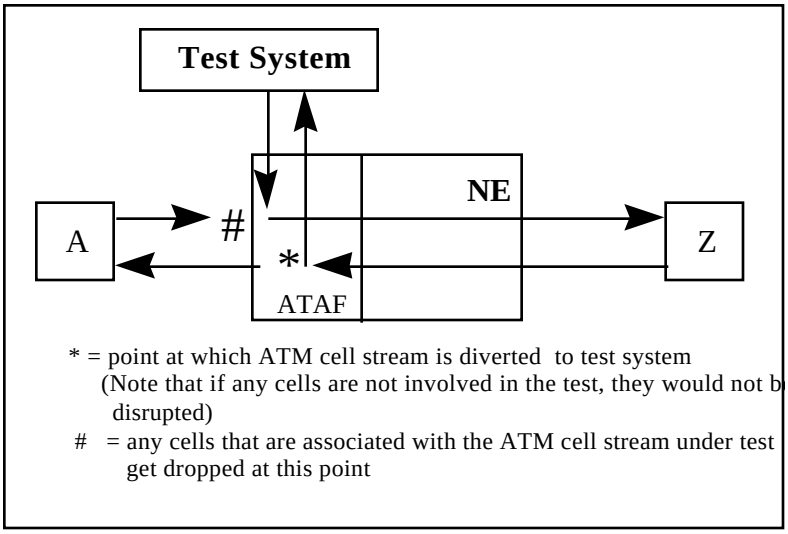

Figure 2-4. "Full-Splitting" Test Access
(Split Direction is Towards NE (Optional))

2.3 ATAF-SDC Requirements

2.3.1 ATAF-SDC Functional Requirements

The data capture activity applies to both the receive and transmit side of ATM Access and Interoffice signaling channels, and it consists of maintaining a log of SSCOP PDUs and a log of information about related timer expiration events. The timer expirations may be for SSCOP timers or timers related to a higher protocol level. Such a log may be activated for an SSCOP connection to gather diagnostic information. It may be activated when a problem is observed, or, more pro-actively, a log may be activated on selected signaling channels on an ongoing basis so maintenance personnel will have immediate access to diagnostic information. This alternative may be invoked when an problem is suspected. The pro-active approach may require more simultaneous logs and hence more resources.

In order to fully understand a sequence of states at one end of an SSCOP connection to diagnose problems, it is important to know the order in which PDUs were sent, received, and when timers expired. This allows analysis of the state transitions that occurred. Thus, a single log is indicated.

(R) SDC-1 ATAF-SDC shall be provided by ATM NEs and requires the support of a log that monitors both the transmit and receive direction of a signaling channel. The logging capability shall be activated/deactivated independently from any other protocol monitoring activities. When the log is full, new information shall replace the oldest information in the log. The ATM NE shall be capable of logging SSCOP PDUs and timer expires for at least 10% of its access signaling channels at any given time, and for at least 5 separate interoffice signaling channels at a given time.

- The log shall maintain entries for the most recent SSCOP PDUs or timer expiries of a connection. For access signaling channels, the log needs to be capable of storing 100 large SSCOP PDUs. For interoffice signaling channels, the log needs to be capable of storing 1000 large SSCOP PDUs. Log information from one SSCOP connection shall not overwrite information from another connection.

- An entry in the log shall be made upon the transmission of an SSCOP PDU, upon the receipt of any SSCOP PDU, or upon expiry of any local SSCOP timer.

- An entry in the log shall be made upon expiry of any local DSS2 timer.

- An entry in the log shall be made upon expiry of any local BISUP timer.

- There are two types of log entries: SSCOP PDUs and timer expiries. When PDUs are logged, entries shall contain the following:

    1. Timestamp (time of log entry, accurate to the nearest ms, according to the local clock). The timestamp shall preserve the actual sequence of events.
    2. PDU. For data PDUs (SD PDU, UD PDU and MD PDU), only the last 32 octets of the information field would need to be logged to get information about SSCOP operation. However, *the entire PDU shall be logged in order to support analysis of the operation of higher-layer PDUs within the SSCOP PDUs (e.g., DSS2 or BISUP).*
    3. Whether PDU was sent or received.

- The log entry for a timer expiry event shall be as follows:

    1. Timestamp (time of log entry, accurate to the nearest ms, according to the local clock). The time recorded shall preserve the actual sequence of events.
    2. Timer identifier
    3. Timer value.
    4. Signaling Identifier for BISUP timer expiries
    5. Call Reference ID for DSS2 timer expiries

Some Additional Information

An estimate of the memory requirements follows. The SSCOP log needs to be capable of logging a modest number of worst case (i.e., big) messages such as SETUP and IAM, which can be on the order of 250 octets. For access signaling channels, in order to store 100 SSCOP PDUs, the log would need on the order of 25,000 octets of memory. For interoffice signaling channels, the log would need on the order of 250,000 octets of memory to store 1000 large SSCOP PDUs.

(R) SDC-2 ATAF-SDC shall be non-intrusive and not affect other data in the NE's connections.

2.3.2 ATAF-SDC NMS Interface Requirements

(R) SDC-3 ATAF-SDC shall allow a Management System to activate/deactivate the logging capability and to retrieve the data that has been logged.

3. M4 "NE View" Logical MIB

3.1 MIB to Support ATAF-VC and ATAF-PP

Figure 3-1 provides a summary of the ATAF managed entities.

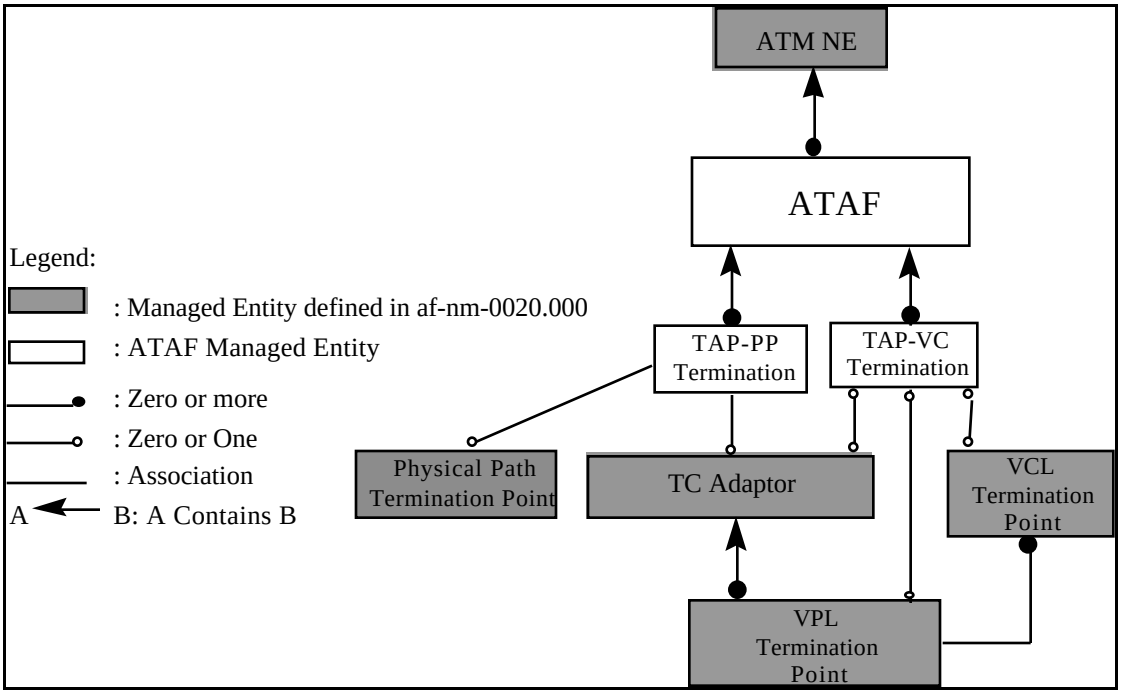

Figure 3-1. Managed Entity Relationship Diagram

The ATAF (with type VC) and TAP-VC Termination managed entities shall be supported by all ATM NEs. The ATAF (with type PP) and TAP-PP Termination managed entities only need to be supported by ATM NEs that support the optional ATAF-PP Control Link Interface (see Section 2.1.3).

For Virtual Connection Access, the ATM NE would support a single instance of the ATAF (with type VC) managed entity and multiple instances of the TAP-VC Termination managed entity. Permanent VCLs and VPLs (represented by instances of the VCL Termination Point and VPL Termination Point managed entities) would be set up between the ATM NE and the Testing System. Each of these VCLs and VPLs would be associated with an instance of the TAP-VC Termination managed entity. The resource to be accessed (for monitoring and/or testing) would be represented by the ResourceID of the TAP-VC Termination managed entity.

For Physical Port Mirroring, the ATM NE would support an additional instance of the ATAF managed entity (this second instance would be with type PP) and multiple instances of the TAP-PP Termination managed entity. Permanent high-speed facilities (represented by instances of the Physical Path Termination Point managed entity) would be set up between the ATM NE and the Testing System. Each Physical Path Termination Point would be associated with an instance of the TAP-PP Termination managed entity. The resource to be accessed (for mirroring) would be represented by an instance of the TC Adaptor managed entity.

3.1.1 ATAF

This managed entity represents the ATAF (VC or PP) functionality within the ATM NE. It is inherently created by the ATM NE. A single instance of type VC will be present in all ATM NEs. A second instance of type PP will be present only when the NE supports the ATAF-PP Control Link Interface (see Section 2.1.3).

Attributes:

ATAF Id: This read-only attribute provides a unique name for each instance of the ATAF
managed entity.

ATAF Type: This read only attribute identifies whether the ATAF managed entity is of type VC or PP.

Operational State: This read-only attribute identifies whether or not the ATAF is capable of performing its normal functions (i.e., in-service or out-of-service).

Administrative State: This read/write attribute is used to activate (unlock) and deactivate (lock) the ATAF function performed by this managed entity. A request to lock the ATAF
function may result in a transition to the shutting down state before the locked state can occur.

Usage State: This read-only attribute identifies whether or not the ATAF is idle, active, or
busy. Idle is the state in which no data streams are being accessed from the NE. Active is the state in which one or more data streams are being accessed from the NE (expect when the busy state has been reached). Busy is the state in which several data streams are being accessed from the NE such that the NE's capacity to access additional data streams has been exhausted. When busy, the ATAF will reject additional requests for test access.

Actions

Connect TAP: This action will connect one TAP-PP or one TAP-VC to a resource to be tested. Each instance of TAP-PP or TAP-VC is bi-directional but can only be used to monitor one direction of a cell stream. To monitor both sides of a bi-directional cell stream requires the use of two TAP managed entities. The following parameters shall be supplied with this action:

- Resource ID: For ATAF of type VC, this parameter contains TC Adaptor managed entity, the VPI value and Vci value (if needed) for the VP or VC that will be monitored/tested. For ATAF of type PP, this parameter contains the ID of the TC Adaptor that will be mirrored.

- Access Mode: The values to which the Access Mode attribute of a TAP-PP or TAP-VC object selected should be set. Valid values for the TAP-VC are monitor in towards NE, monitor out from NE, split in towards NE, or split out from NE. Valid values for TAP-PP are monitor in towards NE, or monitor out from NE.

- TAP Termination ID: This argument is the identifier of the TAP-VC or TAP-PP Termination used for test access and is an optional parameter. If this parameter is supplied, the ATAF should return an error if the TAP-VC or TAP-PP termination is out of service or busy. If the TAP-VC or TAP-PP Termination is available, the TAP-VC or TAP-PP Termination ID is echoed in the action reply.

- The following shall be supplied in the reply upon successful completion of the action:

    - TAP Termination ID: This parameter is the identifier of the TAP-VC or TAP-PP Termination used for test access.

Notifications

Managed Entity Creation: This notification is used to report the creation of an instance of this managed entity.

Managed Entity Deletion: This notification is used to report the deletion of an instance of this managed entity.

State Change: This notification is used to report changes to the Operational State attribute, the Administrative State attribute, and the Usage State attribute of this managed entity. The notification shall identify the state attribute that changed, its old value, and its new value.

Relationships

One instance of the ATAF managed entity (with type VC) shall be contained in an instance of the ATM NE managed entity. Optionally, a second instance of the ATAF managed entity (with type PP) may be contained in an instance of the ATM NE managed entity.

An instance of this managed entity may contain multiple instances of either the ATM TAP-VC Termination managed entity or the TAP-PP Termination managed entity depending on the value of the ATAF Type attribute.

3.1.2 TAP-PP Termination

This managed entity represents the physical and logical Test Access Path (TAP) that is used between the ATM NE and the test system. It is inherently created by the ATM NE. It may be deleted by the ATM NE or by a management system.

Attributes

TAP-PP Termination Id: This read-only attribute provides a unique name for each instance of the TAP-PP Termination managed entity.

Access Mode: This read-only attribute indicates the direction of the traffic being mirrored by the TAP-PP Termination (monitor in towards NE, or monitor out from NE). It will have a null value when the TAP is not in use.

Resource ID: This read-only attribute indicates the TC Adaptor managed entity under test associated with this TAP. It will have a null value when the TAP is not in use.

Supported By Entity: This read-only attribute indicates the Physical Path Termination Point managed entity that is performing the ATAF-PP functionality.

Operational State: This read-only attribute identifies whether or not the TAP-PP Termination is capable of performing its normal functions (i.e., in-service or out of service).

Administrative State: This read/write attribute is used to activate (unlock) and deactivate (lock) the TAP-PP Termination.

Actions

Disconnect ATM Test Access: This action is used to disconnect test access and return the
resource that was being tested back to its normal state.

Notifications

Attribute Value Change: This notification is used to report changes to attribute values of this managed entity. It applies to the following attributes: Resource ID, Directionality, and Supported By Entity.

Managed Entity Creation: This notification is used to report the creation of an instance of this managed entity.

Managed Entity Deletion: This notification is used to report the deletion of an instance of this managed entity.

State Change: This notification is used to report changes to the Operational State attribute, the Administrative State attribute, and the Usage State attribute of this managed entity. The notification shall identify the state attribute that changed, its old value, and its new value.

Relationships

Multiple instances of this managed entity may exist for each instance of the ATAF managed entity with type PP.

An instance of this managed entity shall be associated with zero or one instances of the TC Adaptor managed entity, and with zero or one instance of the Physical Path Termination Point managed entity.

3.1.3 TAP-VC Termination

This managed entity represents the physical and logical Test Access Paths (TAPs) that are used between the ATM NE and the test system. It is inherently created by the ATM NE. It may be selected by the ATM NE or by a management system.

Attributes

TAP-VC Termination Id: This read-only attribute provides a unique name for each instance of the TAP-VC Termination managed entity.

Resource ID: This read-only attribute indicates the TC Adaptor managed entity, the VPI value and VCI value (if needed) for the VP or VC connection under test that is associated with this TAP. It will have a null value when the TAP is not in use.

Access Mode: This read-only attribute indicates the access mode that the TAP-VC is performing (monitor in towards NE, monitor out from NE, split in towards NE, or split out from NE). It will have a null value when the TAP is not in use.

Supported By Entity: This read-only attribute indicates the VCL Termination Point or the VPL Termination Point managed entity that is performing the TAP functionality.

Operational State: This read-only attribute identifies whether or not the TAP-VC is capable of performing its normal functions (i.e., in-service or out-of-service).

Administrative State: This read/write attribute is used to activate (unlock) and deactivate (lock) the TAP-VC.

Actions

Change Access Mode: This optional used to change the access mode of test access that has already been established. The following parameter shall be supplied with this action:

- Access Mode (monitor in towards NE, monitor out from NE, split out from NE)

Disconnect ATM Test Access: This action is used to disconnect test access and return the resource that was being tested back to its normal state.

Notifications

Attribute Value Change: This notification is used to report changes to attribute values of this managed entity. It applies to the following attributes: Resource ID, Access Mode, and Supported By Entity.

Managed Entity Creation: This notification is used to report the creation of an instance of this managed entity.

Managed Entity Deletion: This notification is used to report the deletion of an instance of this managed entity.

State Change: This notification is used to report changes to the Operational State attribute, the Administrative State attribute, and the Usage State attribute of this managed entity. The notification shall identify the state attribute that changed, its old value, and its new value.

Relationships

Multiple instances of this managed entity may exist for each instance of the ATAF managed entity with type VC.

Instances of this managed entity shall be directly associated with one instance of a TC Adaptor and one instance of either the VCL Termination Point managed entity or the VPL Termination Point managed entity.

An instance of this managed entity may be indirectly associated with another instance of the VPL Termination Point or VCL Termination Point managed entity representing the PVC under test.

3.2 MIB to Support ATAF-SDC

3.2.1 Entity Relationship Diagram

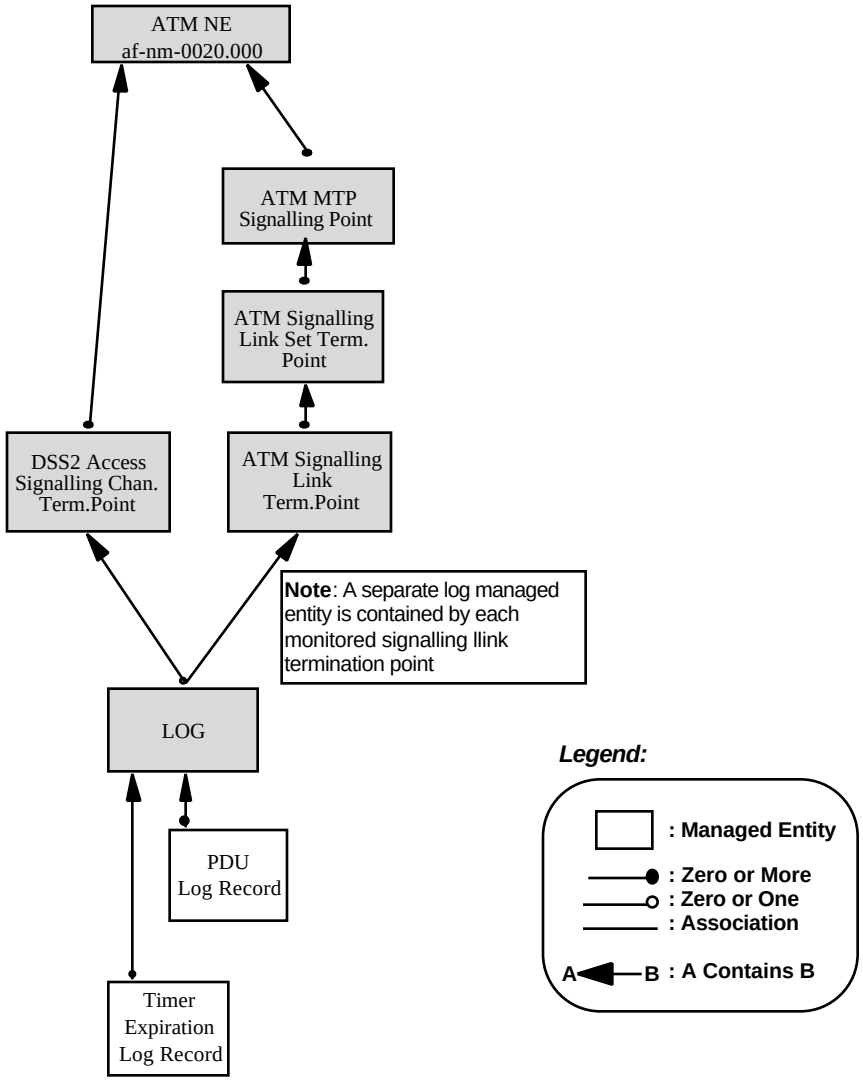

Figure 3-2. Entity Relationship Diagram

3.2.2 Managed Entities

PDU Log Record

This managed entity is used to capture transmitted and received PDUs, e.g., SSCOP received PDUs and SSCOP transmitted PDUs, that are to be retained in a log. It is used to provide information about PDUs that can be used for fault and performance trouble analysis.

Instances of this object are created and deleted by the managed system. An instance of this record is created by the managed system for each PDU that is to be logged. After the log becomes full, the newest record should replace the oldest one regardless of record type

Attributes

Managed Entity ID: This attribute provides a unique name for the managed entity instance in the ATM NE. (R) (mandatory)

Logging Time: This attribute identifies the time that the record was entered into the log accurate to the nearest millisecond. The time must preserve actual sequence of events. (R) (mandatory)

Source Entity: Pointer to the object instance that represents the ATM signaling channel that is the source of the PDU being logged, e.g., a DSS2 Access Signaling Channel Termination Point object for access channel SSCOP PDUs, or an ATM Signaling Link object for interoffice SSCOP PDUs. (R) (Mandatory)

Event Type: Identifies type of event or abnormality, if any, that caused logging of the PDU information The event type should distinguish between received and transmitted PDUs. (R) (Mandatory)

PDU Octets: Entire contents of the PDU to be retained in the log. (R) (Mandatory)

Actions

No actions have been defined for this managed entity.

Notifications

No notifications have been defined for this managed entity.

Relationships

One record is created for each PDU to be logged. A separate instance of the Log managed entity should be created for: (1) each monitored access signaling channel (up to 10 percent of all access signaling channels terminated on the ATM NE), and (2) for up to five monitored interoffice signaling channels. A single log should be created for SSCOP received PDU Log Records, SSCOP transmitted PDU Log Records, and Timer Expiration Log Records for both the receive and transmit sides of each monitored signaling channel. Space for 100 SSCOP PDU Log Records shall be retained in the log for each monitored ATM access signaling channel, and space for 1000 SSCOP PDU Log Records shall be retained for each monitored ATM interoffice signaling channel.

Timer Expiration Log Record

This object class is used to log timer expirations. Instances of this object class provide information about timer expirations that can be used for fault and performance trouble analysis.

An instance of this record is created by the managed system for each timer expiration event that is to be logged. After the log is full, the newest record shall replace the oldest one regardless of record type.

Attributes

Call Reference ID: The Call Reference value associated with a DSS2 timer expiry. (R) (Mandatory for DSS2 timer expiries only)

Managed Entity ID: This read-only attribute provides a unique name for the managed entity instance in the ATM NE. (R) (mandatory)

Logging Time: This attribute identifies the time that the record was entered into the log accurate to the nearest millisecond. This time must preserve actual sequence of events. (R) (mandatory)

Signaling Identifier: The value of the Signaling Identifier for a BISUP timer expiry. (R) (Mandatory for BISUP timer expiries only)

Source Entity: Pointer to the object instance that represents the source of the event logged, e.g., an DSS2 Access Signaling Termination Point object for DSS2 timers, an ATM Signaling Link object for BISUP timers, or either a DSS2 Access Signaling Channel Termination Point or an ATM Signaling Link Termination Point for SSCOP timers. (R) (Mandatory)

Timer Type: Identifies the timer that expired. (R) (Mandatory)

Timer Value: Identifies the value of the timer when it expired (R) (Mandatory)

Actions

No actions have been defined for this managed entity.

Notifications

No notifications have been defined for this managed entity.

Relationships

One record is created for each timer expiration event. A separate instance of the Log entity should be created for: (1) each monitored access signaling channel (up to 10 percent of all access signaling channels terminated on the ATM NE), and (2) for up to five monitored interoffice signaling channels. A single log should be created for SSCOP received PDU Log Records, SSCOP transmitted PDU Log Records, and Timer Expiration Log Records for both the receive and transmit sides of each monitored signaling channel.

4 . M4 CMIP MIB

The following containment diagram, inheritance diagram, managed object classes, conditional packages, attributes, name bindings, actions, and ASN.1 productions are a supplement to the existing ATM Forum CMIP Specification for the M4 Interface described in af-nm-0027.000.

Appendix A

A1. Maintenance of the Signaling Channel

This is an informational appendix that motivates how ATAF can be a valuable tool in performing maintenance of ATM signaling channels. The appendix discusses maintenance of the ATM Access signaling channel, however, similar concepts would also apply to maintenance of ATM Interoffice signaling channels.

The general approach to maintenance of the signaling channel (and isolation of troubles in particular) is as follows:

- for each protocol layer, utilize the performance/protocol monitoring capabilities supported by the ATM NE,
- when the above are not sufficient, utilize the ATM Test Access Function (ATAF) monitoring mode, and finally
- when the above are not sufficient, utilize the ATAF full-splitting mode.

While the information available via the monitoring capabilities of the ATM NE is very helpful, it also is somewhat limited (due to processing and storage limitations of the NE) and thus using the ATAF monitoring mode capability can provide a more detailed view of PDU exchanges that are occurring (and their associated abnormalities/errors). The ATAF full-splitting mode allows a test equipment (that is known to function properly) to be inserted in place of the suspected faulty equipment (either NE or CPE) to conclusively verify that the piece of equipment that was removed during the test was in fact the source of the trouble.

Figure A-1 shows how signaling messages are exchanged between the ATM NE and the CPE over the UNI. Trouble isolation at each protocol layer (as shown in Figure A-1) is discussed in the following subsections.

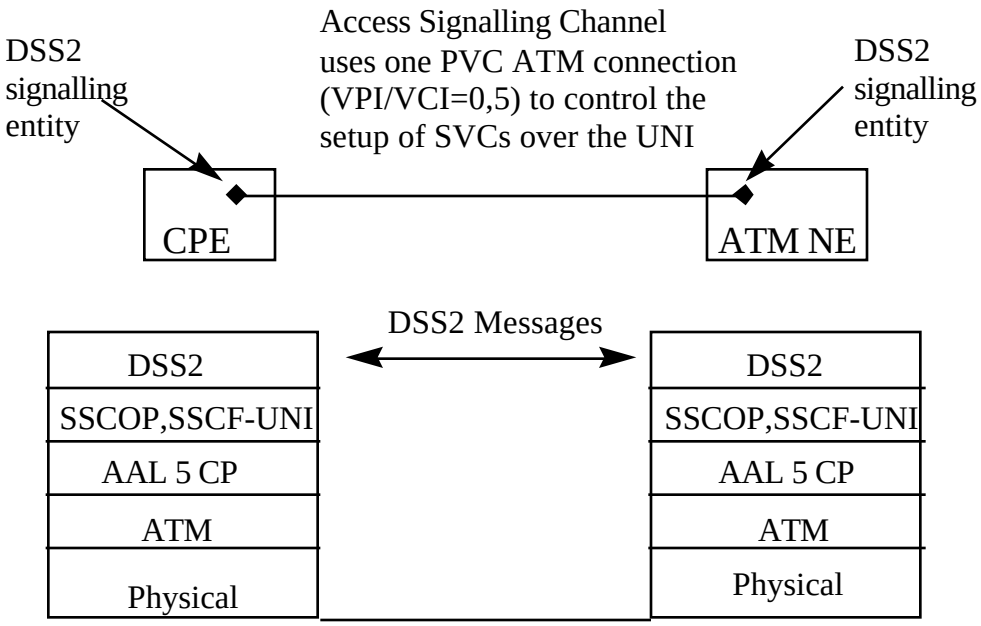

Figure A-1. Access Signalling on a UNI

A1.1 ATM Layer

Troubles that may occur at the ATM Layer are not expected to be unique to the signaling channel. Physical Port Mirroring will probably be the most useful type of test access for diagnosing ATM Layer troubles.

A1.2 AAL Type 5 (Common Part)

According to the protocol monitoring requirements in af-nm-0071-000 (AAL Management for the M4 "NE View" Interface), one counter is used to count the "sum" of any of the following invalid errors: invalid Common Part Indicator (CPI), oversized received Service Data Unit (SDU), and length violation. The ATAF-VC monitoring mode would provide a greater degree of visibility to determine exactly which invalid error was occurring.

A1.3 SSCOP/SSCF-UNI

Annex A of the SSCOP standard (Q.2110) defines a list of 24 different error conditions that may occur at the SSCOP layer. According to the ATM Forum SSCOP protocol monitoring, two separate SSCOP protocol monitoring counters are defined to count the "sum" of different types of errors, i.e., SSCOP Connection Monitoring Counter, and SSCOP Errored PDUs. The ATAF Signaling data Capture (ATAF-SDC) can be used to gain visibility into a explicit log of SSCOP PDUs and a log of information about related timer expiration events.

A1.4 DSS2

Note: DSS2 protocol monitoring requirements have not yet been addressed in ATM Forum network management requirements.

According to Bellcore GR-1248-CORE, Issue 3, the following DSS2 abnormalities can occur:

- Abnormal call/connection termination - A call/connection can be abnormally terminated by unrecoverable conditions that cause termination of the call/connection, or dropping of one of its parties, by issuing a RELEASE, RELEASE COMPLETE, ADD PARTY REJECT or DROP PARTY messages. These messages contain a Cause field that indicates the condition causing the termination (including timer expires) and are issued either in response to an offending message or as a result of a problem in the network or at the other end of the call/connection.

- Status errors - In some instances, a message with errors is received that does not cause termination of the call/connection. In these cases, a STATUS message with a cause field is used to respond to the offending message.

Section 5.4.5.15 of UNI 3.1 lists over 40 different cause field values. Note that although this "cause field" information is present in the signaling PDUs, there is no guarantee that the CPE will process this information and make it available to the user. Therefore, it would be very advantageous if this "cause field" information were available to a craftperson that is trying to resolve a customer complaint.

GR-1248-CORE defines seven protocol monitoring counters that count sum of errors information (derived from the 40+ possible cause field values). The GR further states:

- The ATM NE shall allow a Management System to activate/deactivate the protocol monitoring counting and thresholding capabilities...on a given access signaling channel. At any given time, signaling entity performance monitoring shall be available for an arbitrary subset of at least 10% of all active access signaling channels.

GR-1248-CORE also discusses logs of DSS2 Timers and states:

- The ATM NE shall be capable of supporting, for each access signaling channel, one DSS2 protocol log of DSS2 timers (i.e., timer expiry events). The ATM NE shall allow a Management System to activate/deactivate the logging capability for a given access signaling channel. The logging capability shall be activated/deactivated independently from the protocol monitoring activities.....

The log of DSS2 timers expiries is provided as part of the ATAF Signaling Data Capture (ATAF-SDC) functionality described in Section 2.3.
